
was unknown, despite intense and continuing public interest. Then in April 1989, members of the Historical Maritime Group of New England found wreckage more than 300 feet deep that they were certain had been the Portland. Because of the depth, however, the discoverers were unable to obtain photographs or other evidence that could confirm their find. Thirteen years later, on August 29, 2002, the U.S. Commerce Department's National Oceanic and Atmospheric Administration (NOAA) confirmed that the wreck of the Portland had been found within NOAA's Stellwagen Bank National Marine Sanctuary. Using side-scan sonar and a remotely operated vehicle (ROV), scientists obtained high-quality video and side-scan images in a joint research mission of the Stellwagen Bank National Marine Sanctuary and the National Undersea Research Center at the University of Connecticut.

Storms can usually be classified into one of two types: extratropical cyclones and tropical cyclones. Extra-tropical cyclones are "ordinary" storms formed by the intersection of warm and cold air masses, and can form over land and water in midlatitudes at all times of the year. The temperature difference or gradient between the air masses is the major source of energy for these storms. Tropical cyclones include hurricanes and typhoons, and are formed mainly during summer and fall over warm tropical oceans. Warm humid aid in these regions is loaded with water vapor that condenses as it rises into cooler air in the atmosphere. Condensation releases latent heat of vaporization, and this heat is the primary source of energy for tropical cyclones.

Occasionally, an extratropical cyclone will develop some of the characteristics of a tropical cyclone. This hybrid storm forms when thunderstorms begin to generate near the storm's center. When this happens, the central core of the storm is warmed as latent heat is released by water vapor condensing in the thunderstorms. Pressure in the core of the storm drops-sometimes very rapidly-and cre-
ates gale-force or hurricane force winds. The rapid drop in pressure is called "explosive deepening;" if the pressure steadily falls one millibar per hour for 24 hours or more, the storm is called a "bomb cyclone." At the same time, a tight temperature gradient is maintained on the northern side of the storm (in the northern hemisphere).

Typical weather patterns in New England states during late October and November are conducive to the formation of massive storms. At this time of the year, large cold air masses from Canada cross the midwestern states on a regular basis. At the same time, the Atlantic Ocean retains its summer heat and these warm waters sometimes spawn hurricanes. When the east-moving cold air masses encounter the warm, humid oceanic air, the result is what New Englanders call "Nor'easters:" storms that are often severe, and are often the cause of maritime disasters.

The Gale of 1989 (sometimes called the "Portland Gale") began as three air masses: an area of high pressure over the Ohio valley, a weak low-pressure area near Minnesota, and another low over the western Gulf of Mexico. By the evening of November 24, the high pressure area and Great Lakes low had both moved eastward. With the counterclockwise (cyclonic) circulation typical of air masses in the northern hemisphere, the Great Lakes low drew in Arctic air from central Canada, lowering temperatures dramatically across the northern plains. To the south, the Gulf of Mexico low was spreading rain across the southern states from Lovisiana to Georgia.

By the morning of November 26, the high pressure area was off the New England coast, the Great Lakes low was centered over Detroit, and the southern low was just off the coast of South Carolina. At this point, the two low-pressure air masses were connected by an elongated area of low pressure known as a trough, which facilitated energy exchange between the air masses. As the Great Lakes low continued its eastward advance,
the southern low began to move up the east coast, gradually gaining strength and speed. By three o'clock, the southern low had almost completely absorbed the Great Lakes system and was spinning off Norfolk. As the weather system continued to grow, large amounts of moisture absorbed from the Gulf Stream became a massive snowfall that extended from Washington, DC to New York City.

As the storm moved north, a steep pressure gradient developed between the low pressure storm system and the area of high pressure to the northeast, as well as between the storm system and the Arctic high to the northwest of the storm. The result was unusually strong gales that battered central and southern New England for the entire day on November 27. By Monday, November 28, the storm had moved off to the northeast, leaving below-freezing temperatures, a devastated coastline, and shocked communities that only gradually learned of the Portland's fate.

In this lesson, students will research the history of a more recent and familiar storm: the Halloween Nor'easter of 1991, also known as "The Perfect Storm." The purpose of this lesson is to acquaint students with some sources of meteorological information that can provide historical as well as realtime data on weather events.

## Learning Procedure

1. You may want to download a copy of "The Portland Gale" from http://www.hazegray.org for more information on the Portland and the monster storm of 1898. Visit hitp://oceanexplorer.nooa.gov for up-to-date information on the 2003 Steamship Portland expedition.
2. Briefly review the story of the Portland and the gale of 1898. Using an overhead transparency of the eastern United States, sketch and discuss the weather systems that produced this storm.
3. Tell students that their assignment is to prepare a written report on the Halloween Nor'easter of
4. You may want to allow them to discover for themselves that this is the famous "Perfect Storm." Their reports should include a chronological narrative of the storm's history, including descriptions of the weather systems that were involved. Reports should also answer the following questions:

- Was this the deadliest storm on record? If not, what was?
- Was this the most expensive storm on record? If not, what was?
- What information did oceanographic data buoys provide about the maximum wind speeds and wave heights associated with the storm?
- Why was the "unnamed hurricane" unnamed?

The following websites have useful information for completing this assignment:
hitp://www.ndbc.noaa.gov/Maps/northeast_hist.html

- National Data Buoy Center website with realtime as well as historical data for data buoys in the northeast
hitp://www.ncdc.nooa.gov/oo/satellite/satelliteseye/cyclones
- National Climactic Data Center with information on extratropical cyclones
hitp://www.nhc.noaa.gov - National Hurricane Center, with historical information on hurricanes

4. Lead a discussion of students' research results. Written reports should include most of the following points:

- Like the Portland Gale, the Halloween Nor'easter of 1991 was the result of a collision between a cold front and a warm low-pressure area moving north along the US east coast.
- The warm low-pressure area developed between October 23 and 25 and on the 25th was located at latitude $27.1^{\circ} \mathrm{N}$, longitude $64.9^{\circ} \mathrm{W}$, with wind speeds of 25 kt .
- Between October 25 and 27 , winds in the warm low-pressure system strengthened steadily to a tropical storm strength ( 60 kt ).
- On October 28, the warm low-pressure system strengthened to 65 kt and was named Hurricane Grace; at the same time, a cold low-
pressure area had moved off the east coast of Nova Scotia, and was strengthening; the low pressure of this cold system caused Hurricane Grace to turn sharply away from its northwest course and move eastward into the cold lowpressure system.
- On October 29, the cold low-pressure system absorbed Hurricane Grace and continued to strengthen, drifting first toward the southeast, and then toward the southwest.
- The storm reached peak intensity on October 30; a strong high pressure system that extended from the Gulf of Mexico along the Appalachians into Greenland contributed to a steep pressure gradient that generated strong winds where this system met the low-pressure area of the storm.
- NOAA buoy 44011 at $41.1^{\circ} \mathrm{N}, 66.6^{\circ} \mathrm{W}$, reported maximum sustained winds of 49 kt with gusts to 65 kt ; NOAA buoy 44011 at $41.1^{\circ} \mathrm{N}, 66.6^{\circ} \mathrm{W}$, reported maximum sustained winds of 49 kt with gusts to 65 kt , and wave heights of $39 \mathrm{ff} ;$ NOAA buoy 44008 at $40.5^{\circ} \mathrm{N}, 69.5^{\circ} \mathrm{W}$, reported maximum sustained winds of 53 kt with gusts to 63 kt , and wave heights of 31 ff ; Canadian buoy 44137 at $42.26^{\circ} \mathrm{N}, 62.0^{\circ} \mathrm{W}$, reported sustained winds of 80 kt and open-water wave heights of 101 ft .
- The southward track of the Halloween Nor'easter of 1991 carried it over the Gulf Stream on October 31. This added heat to the system, and caused a re-strengthening. On November 1, circulation at the center of the Halloween Nor'easter of 1991 reached hurricane intensity. The new hurricane weakened on November 2 and made landfall near Halifax, Nova Scotia later that day as a tropical storm.
- The second hurricane was unnamed because weather officials felt that naming the hurricane would cause major confusion and concern among the media, emergency management officials, and the public. The concern was that people might conclude that an entirely new storm had developed, when it fact it was another phase of the Halloween Nor'easter of

1991 that had already received a great deal of attention because of the destruction it had caused.

- The Halloween Nor'easter of 1991 was not the deadliest storm on record. A hurricane that struck Martinique, St. Eustatius, and Barbados in 1780 is reported to have killed more than 20,000 people.
- The Halloween Nor'easter of 1991 was not the most expensive storm on record. Hurricane Andrew in 1992 was the most expensive, causing more than $\$ 26$ billion worth of damage.

## The BRIDGE Connection

http://www.vims.edu/bridge/archive 1200.htm/
http://www.vims.edu/bridge/dimate.html

## The "Me" Connection

Have students write a short essay describing how real-time or historical meteorological information might be personally useful.

## Connections to Other Subjects <br> English/Language Arts

## Evaluation

Written reports prepared in Step 3 provide an opportunity for assessment.

## Extensions

Log on to hitp:///oceanexplorer.noaa.gov to keep up to date with the latest Steamship Portland discoveries.

## Resources

Bachelder, P. D. and M. P. Smith. 2003. Four Short Blasts. The Gale of 1898 and the Loss of the Steamer Portland. The Provincial Press. Portland, ME.

## National Science Education Standards

Content Standard A: Science as Inquiry

- Abilities necessary to do scientific inquiry
- Understandings about scientific inquiry

## Content Standard B: Physical Science

- Motions and forces
- Interactions of energy and matter

## Content Standard D: Earth and Space Science

- Energy in the Earth system

## Content Standard E: Science and Technology

- Abilities of technological design

## Content Standard F: Science in Personal and Social

 Perspectives- Natural and human-induced hazards
